

Cortex-M Processors - Memory Systems

Lecture 4

Yeongpil Cho

Hanyang University

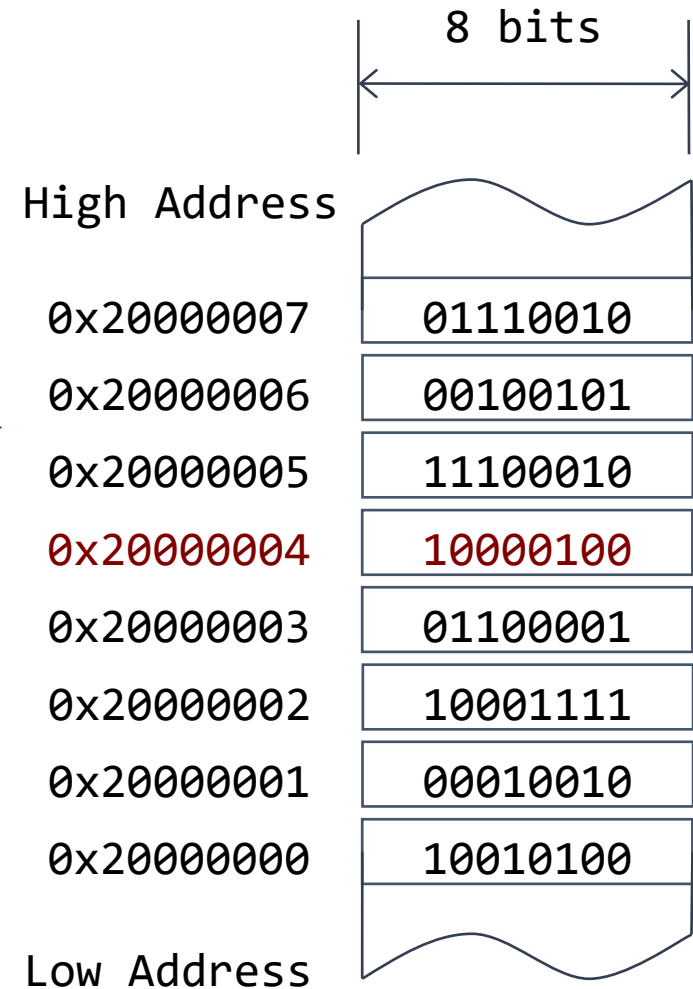

Topics

- Memory Map
- MPU
- Bit-banding
- Miscellaneous features

Logic View of Memory

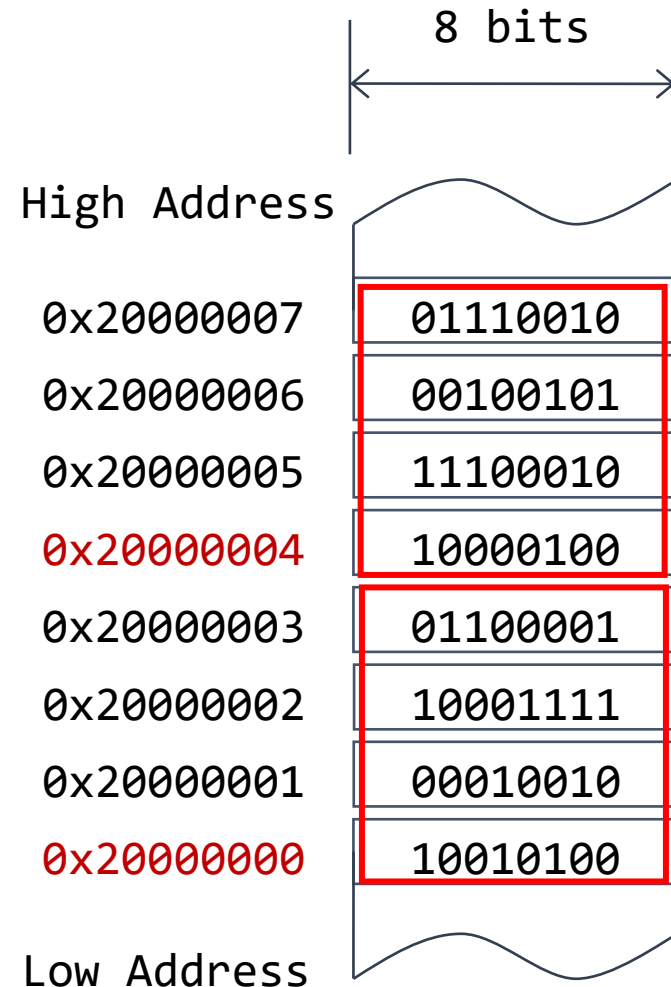

- By grouping bits together, we can store more values
 - 8 bits = **1 byte**
 - 16 bits = 2 bytes = **1 halfword**
 - 32 bits = 4 bytes = **1 word**
- From software perspective, **memory is an addressable array of bytes**.
 - The byte stored at the memory address 0x20000004 is 0b10000100

0b10000100 \longrightarrow 0x84 \longrightarrow 132
Binary Hexadecimal Decimal

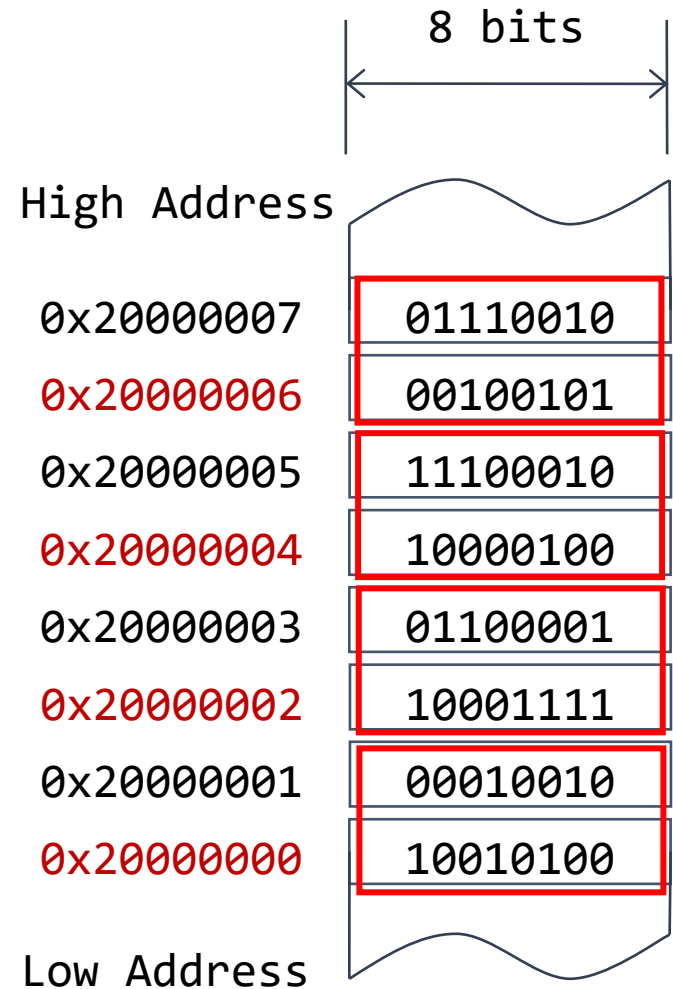

Logic View of Memory

- When we refer to memory locations by address, we can only do so in units of bytes, halfwords or words
- Words
 - 32 bits = 4 bytes = **1 word** = **2 halfwords**
 - Memory address of a word is the lowest address of all four bytes in that word.
 - Two words at addresses:
 - 0x20000000
 - 0x20000004

Logic View of Memory

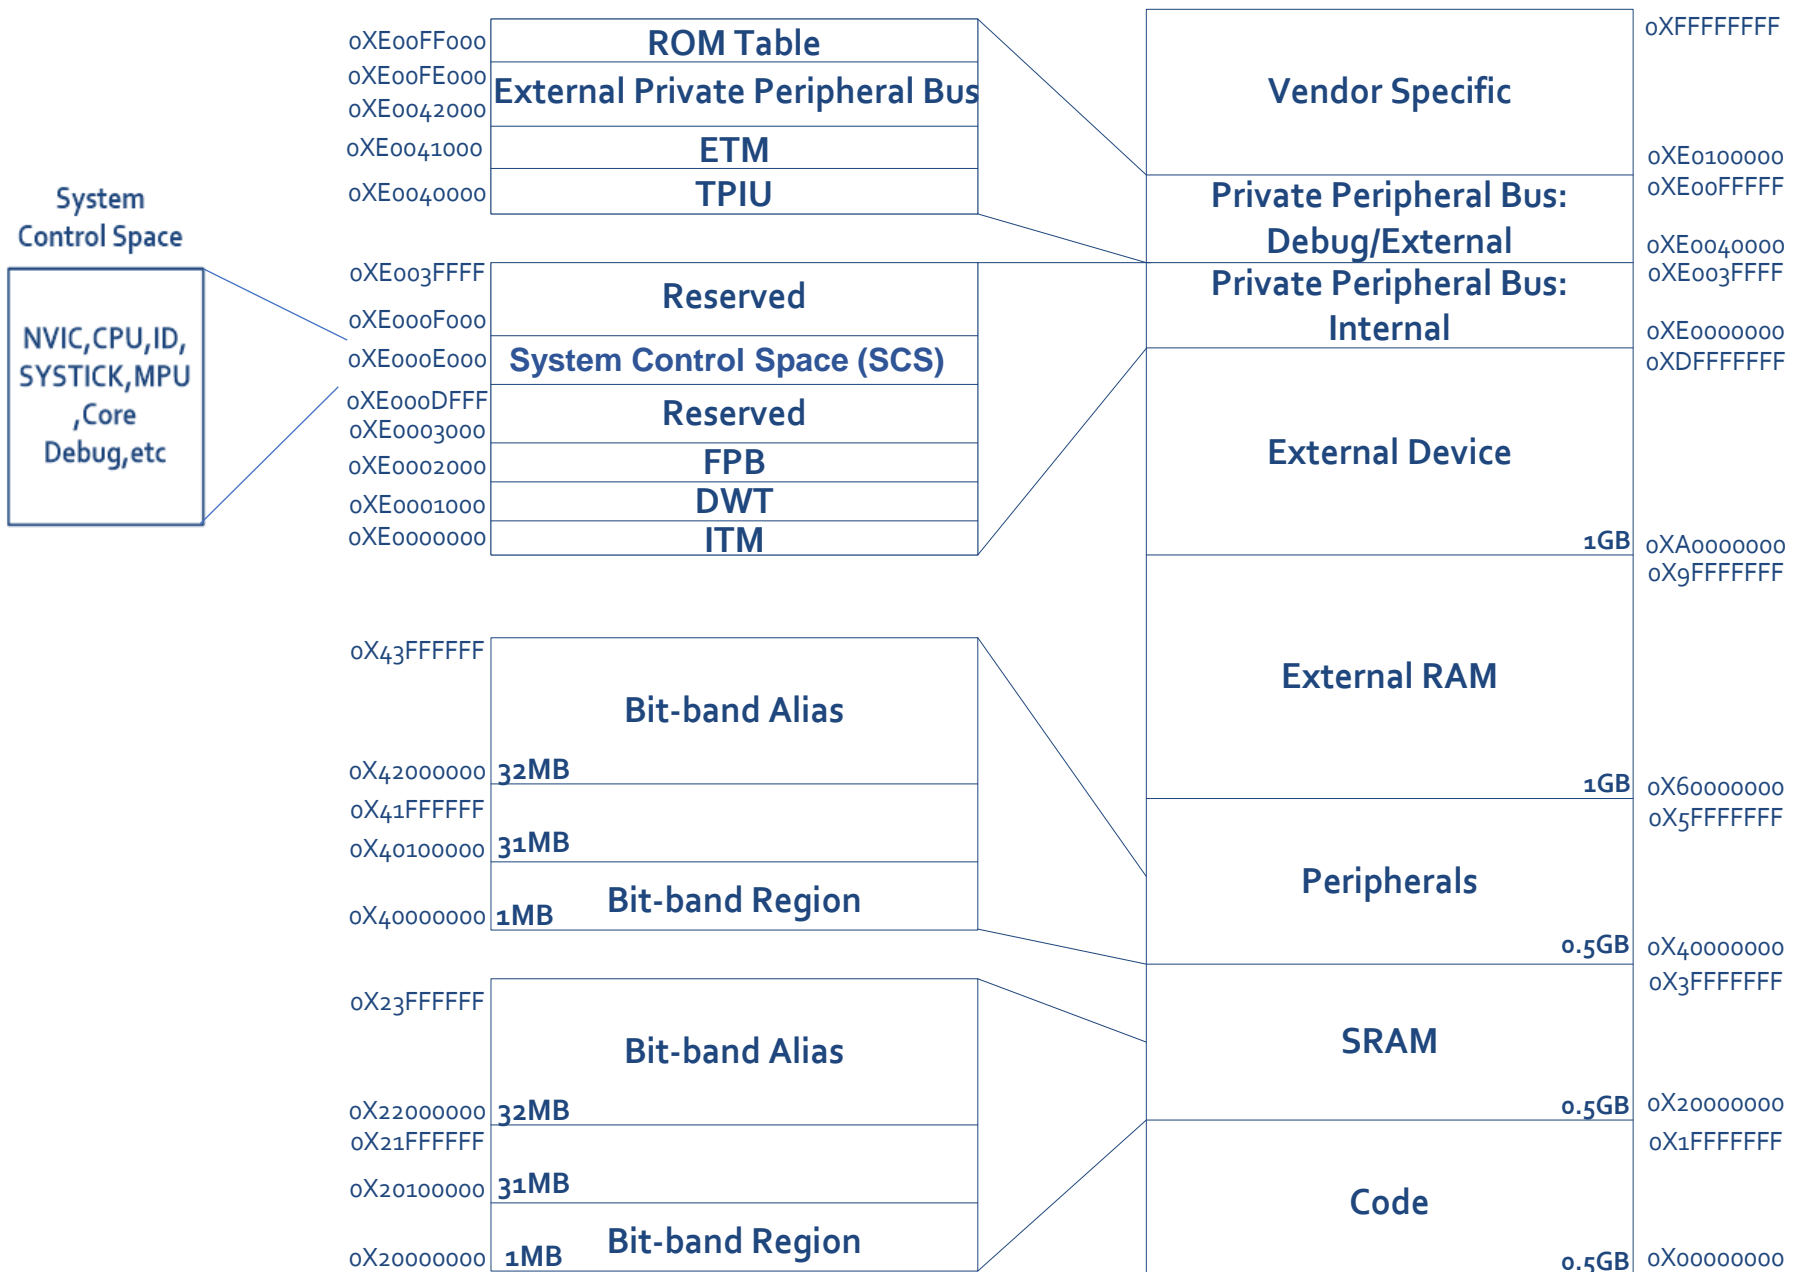

- Halfwords
 - **16** bits = **2** bytes = **1** halfword
 - The right diagram has four halfwords at addresses of:
 - 0x20000000
 - 0x20000002
 - 0x20000004
 - 0x20000006

Memory Map

Memory Maps

- The Cortex-M3 processor has a total of 4 GB of address space.
- The Cortex-M3 processor has a fixed memory map.
 - Easy software porting from one Cortex-M3 product to another
 - For example, Nested Vectored Interrupt Controller (NVIC) and Memory Protection Unit (MPU) have the same memory locations in all Cortex-M3 products

A Cortex-M3 Predefined Memory Map

Memory Access Attributes

- The memory map also defines the memory attributes of accessing each memory block or device:

- Cortex-M3 has the default memory attribute settings
 - can be overridden if MPU is present and the region is programmed differently from the default.

Memory Access Attributes

- Bufferable
 - Write to memory can be carried out by a write buffer while the processor continues on next instruction execution.
- Cacheable
 - Data obtained from memory read can be copied to a memory cache so that next time it is accessed the value can be obtained from the cache to speed up the program execution.
- Executable
 - The processor can fetch and execute program code from this memory region.
- Sharable
 - Data in this memory region could be shared by multiple bus masters. Memory system needs to ensure coherency of data between different bus masters in shareable memory region.

Default Memory Attributes

Region	Address	For	Cacheable	Executable, buffered
Code memory region	0x00000000–0x1FFFFFFF	Code and data as well	cacheable	Executable, write buffered
SRAM memory region	0x20000000–0x3FFFFFFF	On-chip RAM	cacheable	Executable, write buffered
Peripheral region	0x40000000–0x5FFFFFFF	Peripherals	Noncacheable	Nonexecutable
External RAM region	0x60000000–0x7FFFFFFF	Either on-chip or off-chip memory	cacheable	Executable
External RAM region	0x80000000–0x9FFFFFFF	Either on-chip or off-chip memory	cacheable	Executable
External devices	0xA0000000–0xBFFFFFFF	External devices and/or shared memory	Noncacheable	Nonexecutable, nonbuffered
External devices	0xC0000000–0xDFFFFFFF	External devices and/or shared memory	Noncacheable	Nonexecutable, nonbuffered
System region	0xE0000000–0xFFFFFFFF	Private peripherals and Vendor-specific devices	Noncacheable	Nonexecutable, nonbuffered (buffered for vendor-specific memory)

Address Space Division and Attributes

Default Memory Access Permissions

- The Cortex-M3 memory map has a default configuration for memory access permissions
- The default memory access permission is used when either:
 - 1. No MPU is present
 - 2. MPU is present but disabled
- Otherwise, the MPU will determine whether memory accesses are allowed
- When a memory access is blocked, the fault exception takes place immediately.

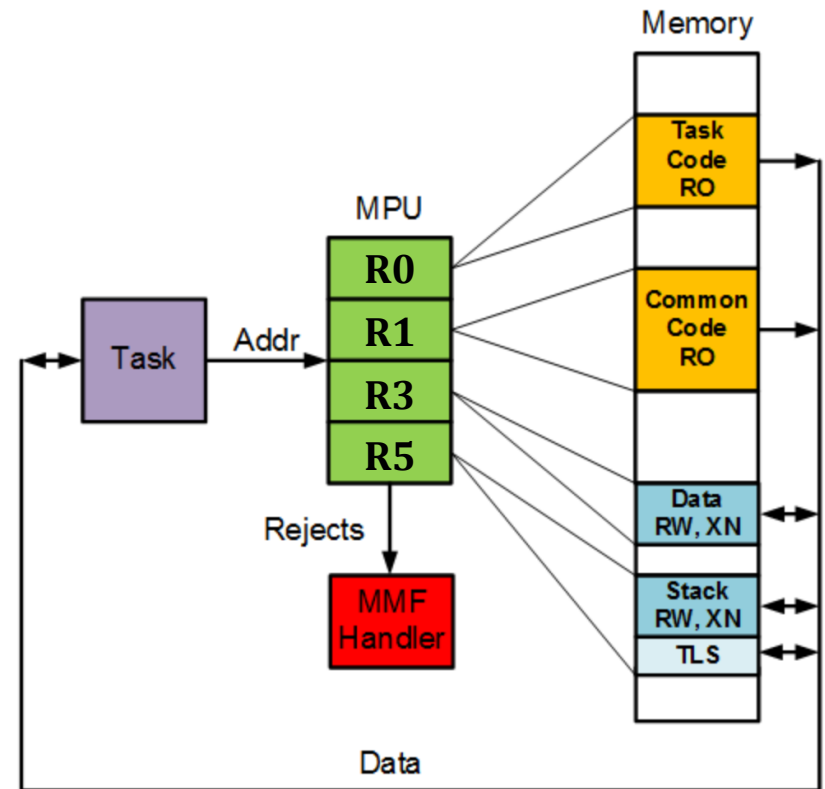

Default Memory Access Permissions

Memory Region	Address	Access in User Program
Vendor specific	0xE0100000–0xFFFFFFFF	Full access
ETM	0xE0041000–0xE0041FFF	Blocked; user access results in bus fault
TPIU	0xE0040000–0xE0040FFF	Blocked; user access results in bus fault
Internal PPB	0xE000F000–0xE003FFFF	Blocked; user access results in bus fault
SCS	0xE000E000–0xE000EFFF	Blocked; user access results in bus fault
FPB	0xE0002000–0xE0003FFF	Blocked; user access results in bus fault
DWT	0xE0001000–0xE0001FFF	Blocked; user access results in bus fault
ITM	0xE0000000–0xE0000FFF	Read allowed; write ignored except for stimulus ports with user access enabled
External Ram	0x60000000–0x9FFFFFFF	Full access
Peripheral	0x40000000–0x5FFFFFFF	Full access
SRAM	0x20000000–0x3FFFFFFF	Full access
Code	0x00000000–0x1FFFFFFF	Full access

MPU

MPU (Memory Protection Unit)

- MPU provides functionality to check memory and I/O accesses are allowed.
 - Supports 8~16 distinct memory regions
 - Each region can be set to some combinations of fetch, read and write permissions.
 - Access attributes as well e.g., cacheability, shareability
- A Trap (exception) arises when access is not permitted
 - MMF: Memory Management Fault

MPU (Memory Protection Unit)

- Combinations of memory access permissions

Privileged Permissions	Unprivileged Permissions	Description
No Access	No Access	All accesses generate a permission fault
RO	No Access	Privileged read only
RO	RO	Un-/Privileged read only
RW	No Access	Privileged access only
RW	RO	Unprivileged writes generate permission faults
RW	RW	Full access

MPU (Memory Protection Unit)

- Regions can be overlapped (ARMv7 only)
 - When memory regions overlap, a memory access is affected by the attributes of the region with the highest number.

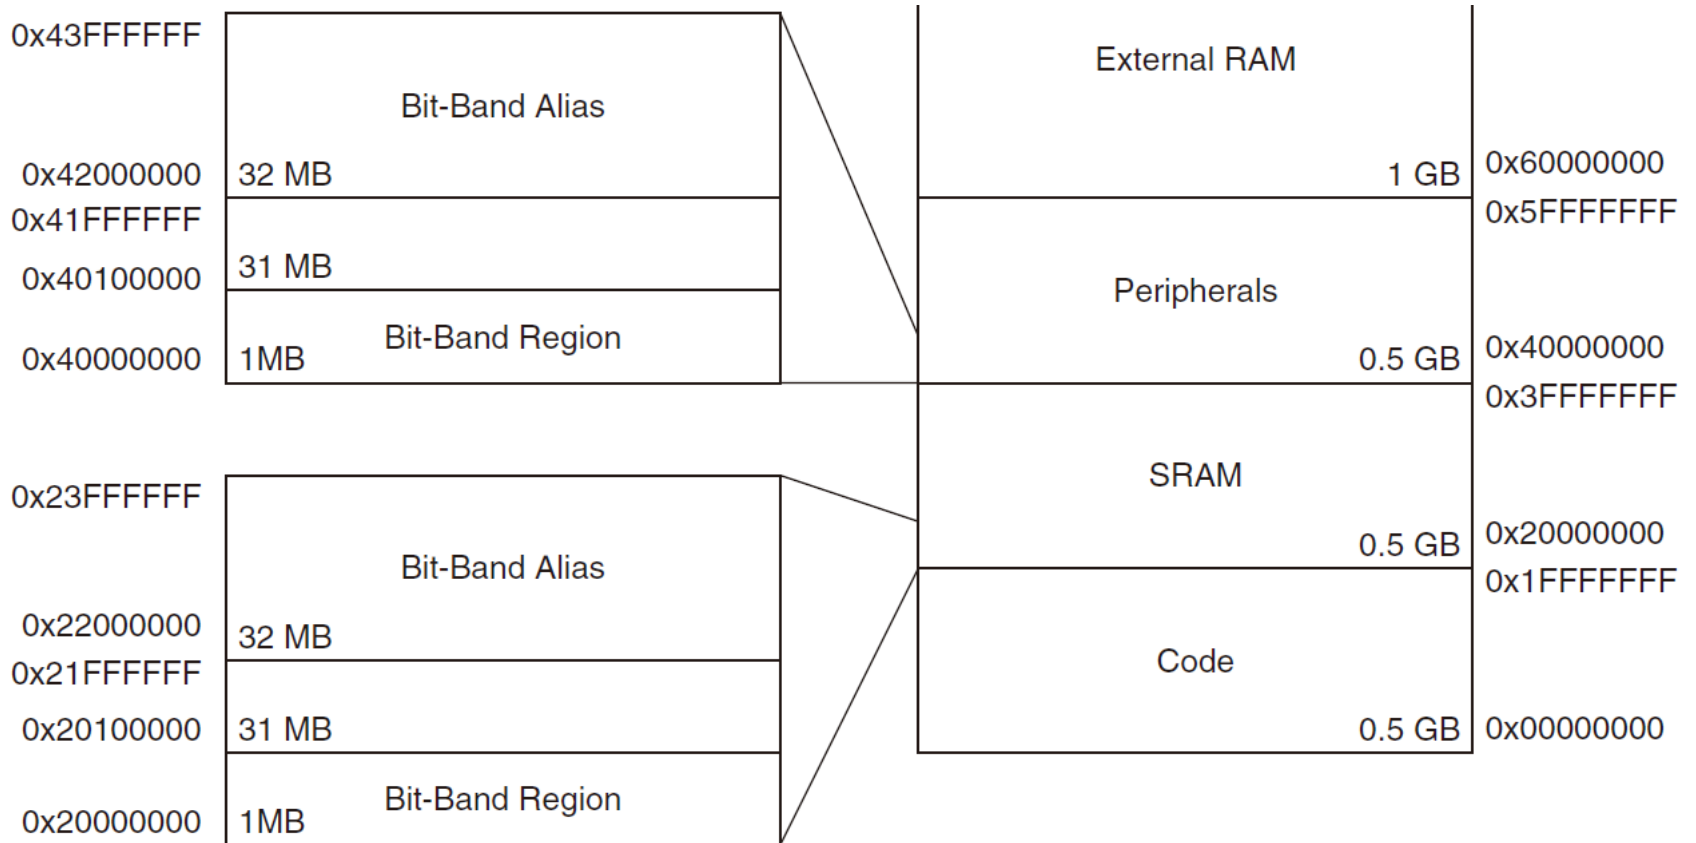

Bit-banding

Bit-Band Operations

- Bit-band operation support allows a single load/store (read/write) operation to access a single data bit.
- Bit-band regions:
 - The first 1 MB of the SRAM region
 - The first 1 MB of the peripheral region
- They can be accessed via a separate memory region called the bit-band alias.
- Bit Banding done transparently by bus matrix.

Bit-Band Region and Bit-Band Alias

Bit-Band Region and Bit-Band Alias

Bit-Band Region	Aliased Equivalent
0x20000000 bit[0]	0x22000000 bit[0]
0x20000000 bit[1]	0x22000004 bit[0]
0x20000000 bit[2]	0x22000008 bit[0]
...	...
0x20000000 bit[31]	0x2200007C bit[0]
0x20000004 bit[0]	0x22000080 bit[0]
...	...
0x20000004 bit[31]	0x220000FC bit[0]
...	...
0x200FFFFC bit[31]	0x23FFFFFC bit[0]

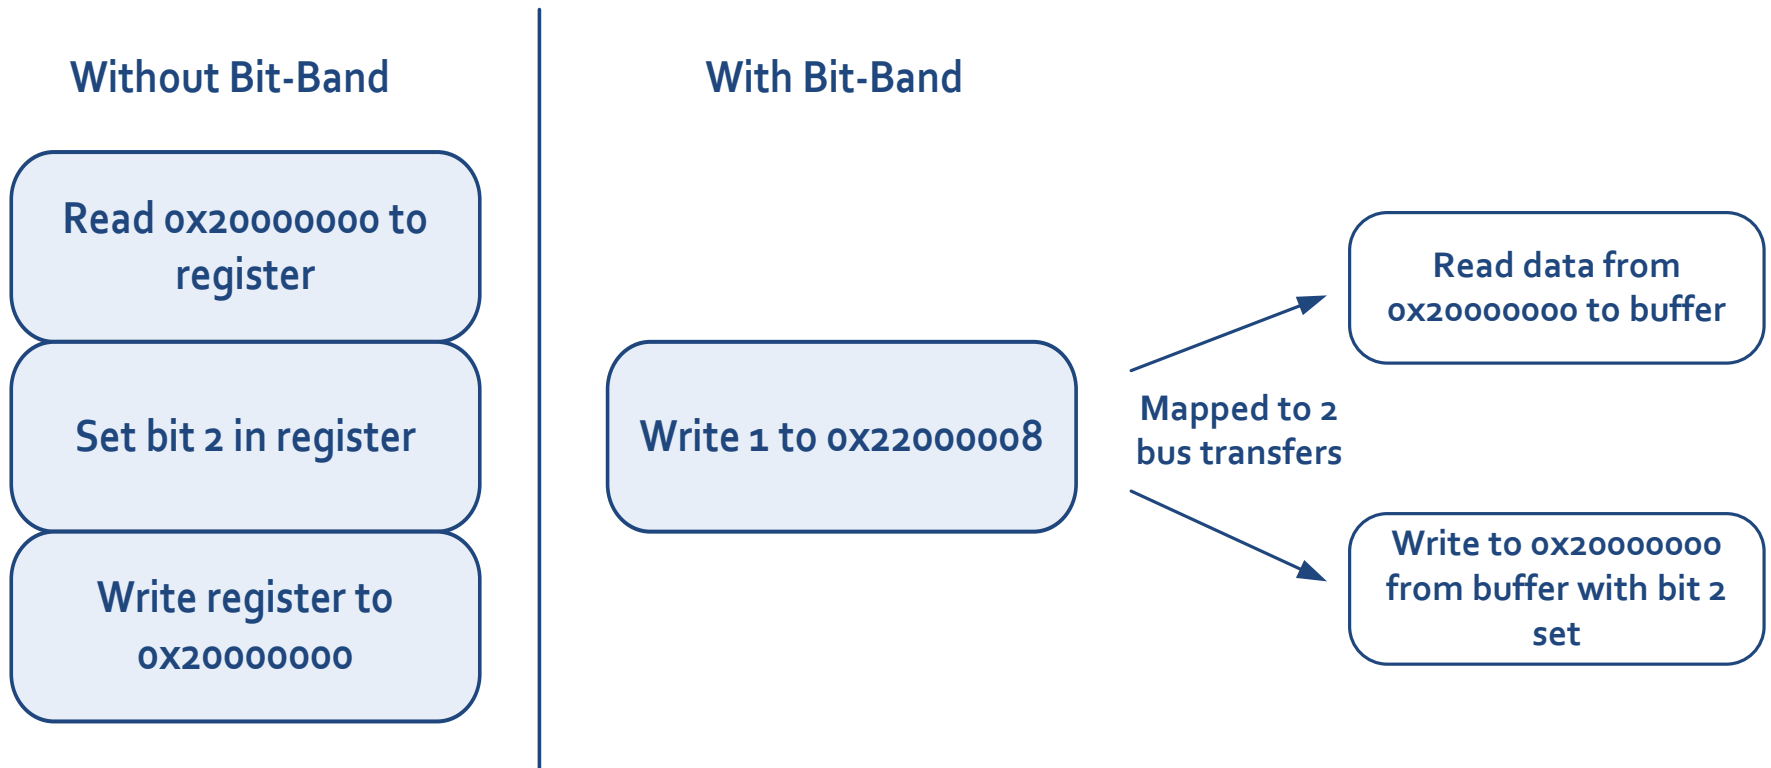

**Remapping of Bit-Band Addresses in
SRAM Region**

Bit-Band Region	Aliased Equivalent
0x40000000 bit[0]	0x42000000 bit[0]
0x40000000 bit[1]	0x42000004 bit[0]
0x40000000 bit[2]	0x42000008 bit[0]
...	...
0x40000000 bit[31]	0x4200007C bit[0]
0x40000004 bit[0]	0x42000080 bit[0]
...	...
0x40000004 bit[31]	0x420000FC bit[0]
...	...
0x00FFFFC bit[31]	0x43FFFFFC bit[0]

**Remapping of Bit-Band Addresses in
Peripheral Memory Region**

Write to Bit-Band Alias

- To set bit 2 in word data in address 0x20000000:
- Write:

Write to Bit-Band Alias

- The assembler sequence to

- Write:

- Without Bit-Band:

```
LDR    R0, =0x20000000 ; Setup address
LDR    R1, [R0]         ; Read
ORR.W  R1, #0x4         ; Modify bit
STR    R1, [R0]         ; Write back result
```

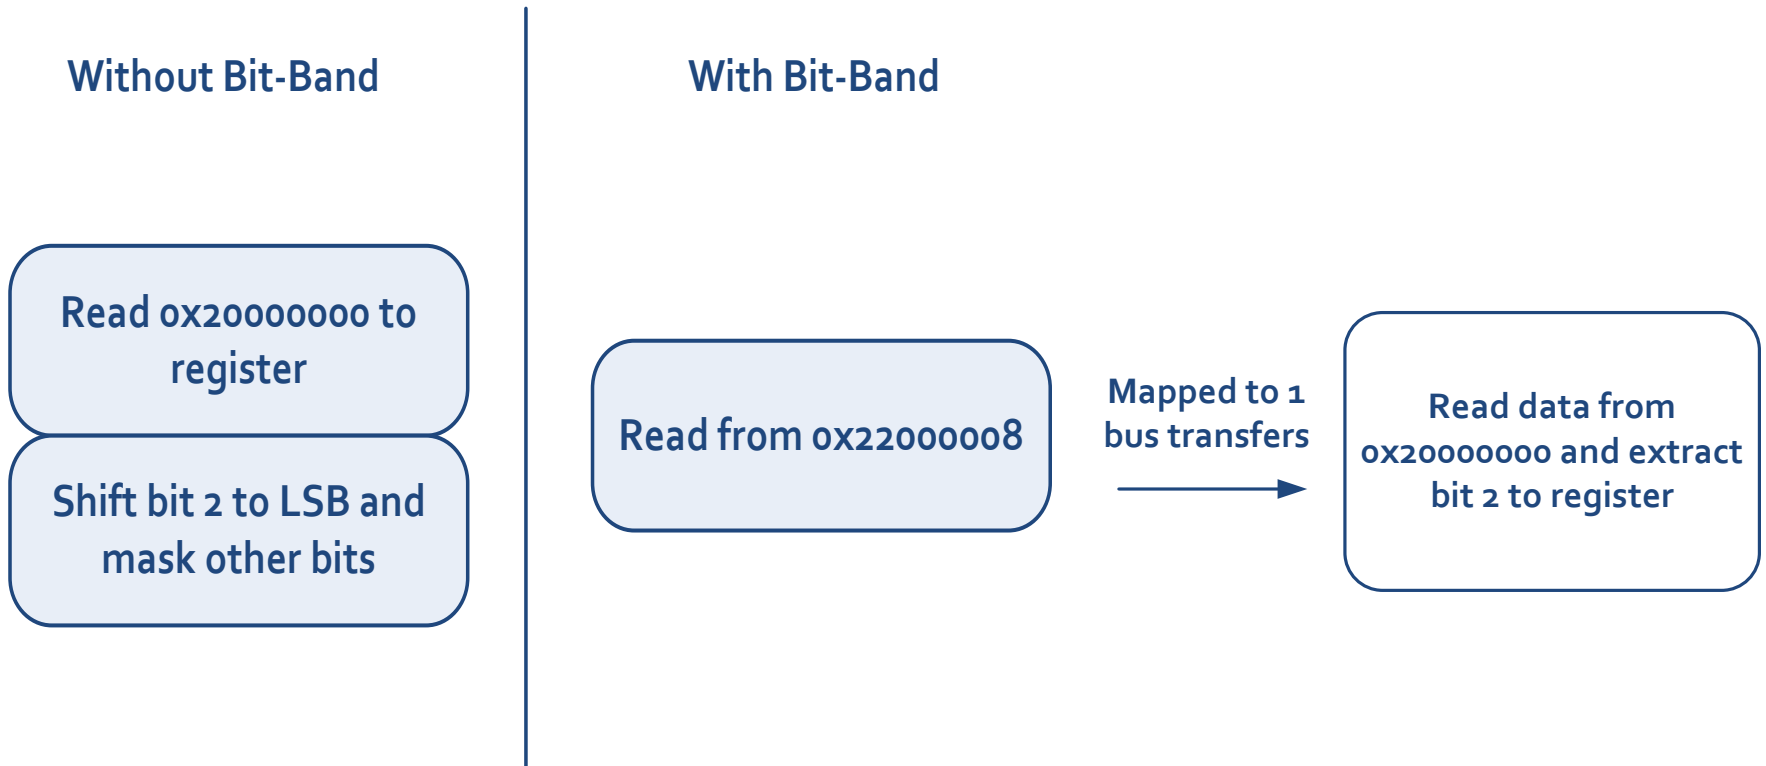

- For write operations, the written bit data is shifted to the required bit position, and a READ-MODIFY-WRITE is performed.

- With Bit-Band:

```
LDR    R0, =0x22000008 ; Setup address
MOV    R1, #1           ; Setup data
STR    R1, [R0]         ; Write
```

Read from the Bit-Band Alias

- Read:

Read from the Bit-Band Alias

- The assembler sequence to read:
- Read:
 - Without Bit-Band:

```
LDR    R0, =0x20000000 ; Setup address
LDR    R1, [R0]         ; Read
UBFX.W R1, R1, #2, #1   ; Extract bit[2]
```

 - For read operations, the word is read and the chosen bit location is shifted to the LSB of the read return data.
 - With Bit-Band:

```
LDR    R0, =0x22000008 ; Setup address
LDR    R1, [R0]         ; Read
```

Advantages of using bit-band operations:

- Faster bit operations with fewer instructions
- Exclusive read/write operations (by hardware)

Figure 5.8 Data Are Lost When an Exception Handler Modifies a Shared Memory Location

Advantages of using bit-band operations:

- Faster bit operations with fewer instructions
- Exclusive read/write operations (by hardware)

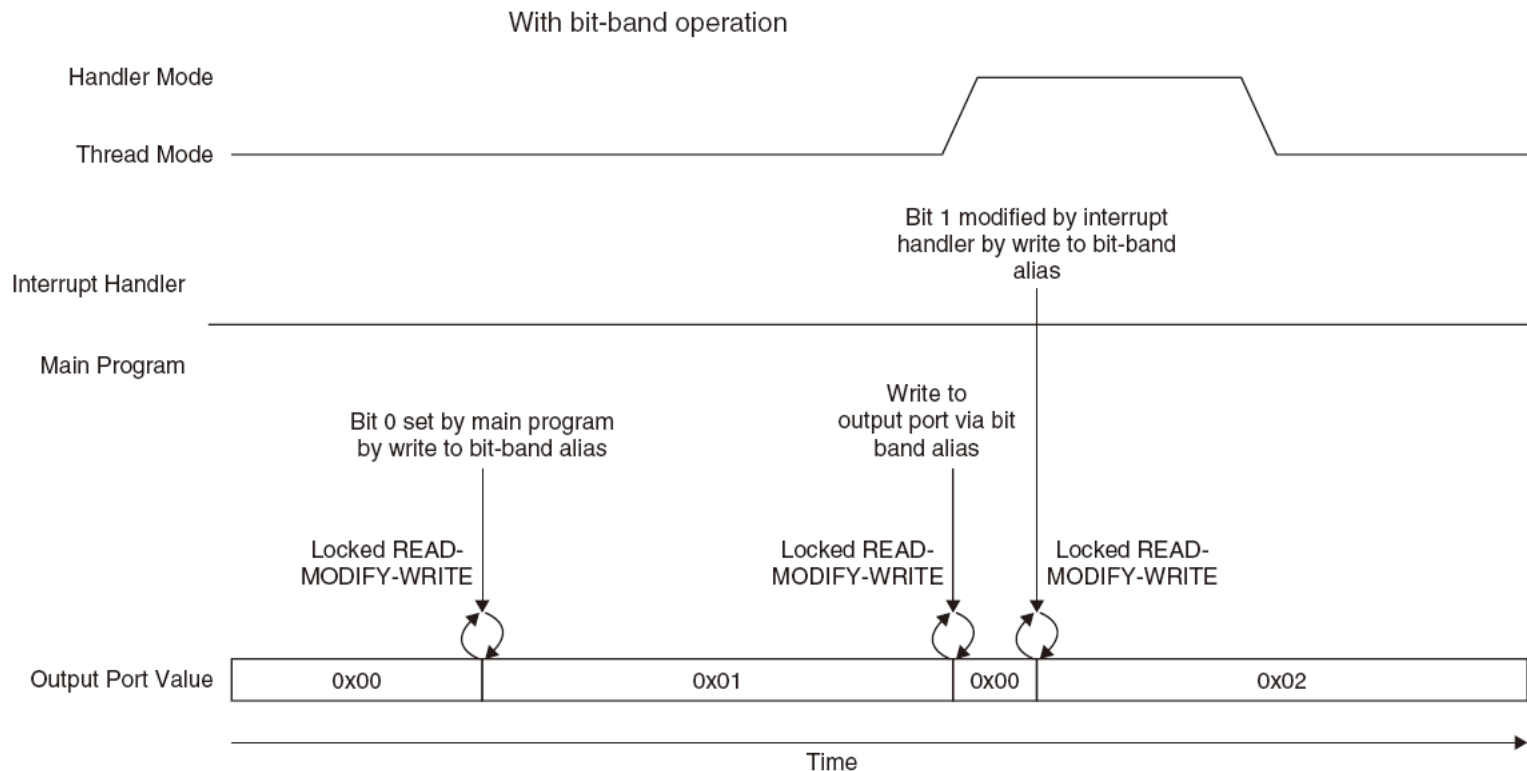

Figure 5.9 Data Loss Prevention with Locked Transfers Using the Bit-Band Feature

Advantages of using bit-band operations:

- Faster bit operations with fewer instructions
- Exclusive read/write operations (by hardware)

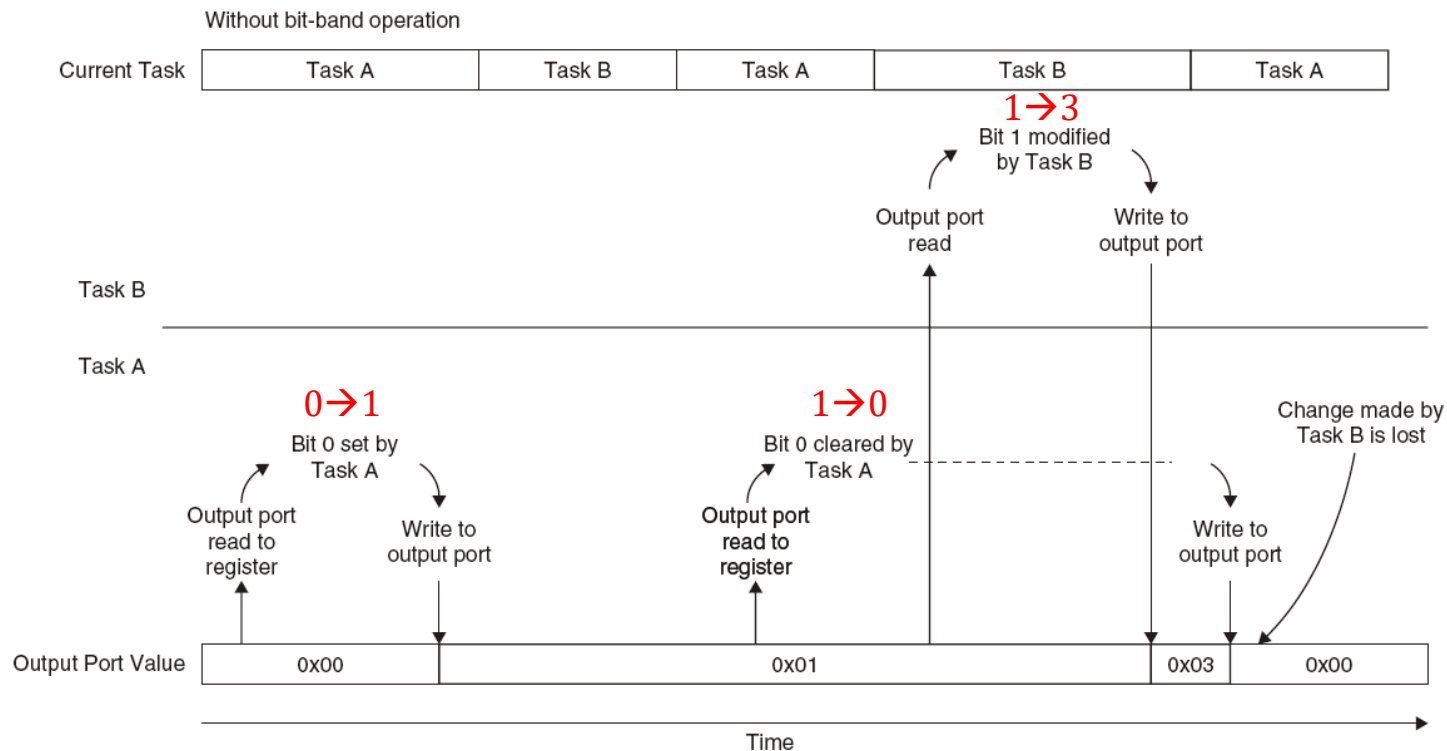

Figure 5.10 Data Are Lost When a Different Task Modifies a Shared Memory Location

Advantages of using bit-band operations:

- Faster bit operations with fewer instructions
- Exclusive read/write operations (by hardware)

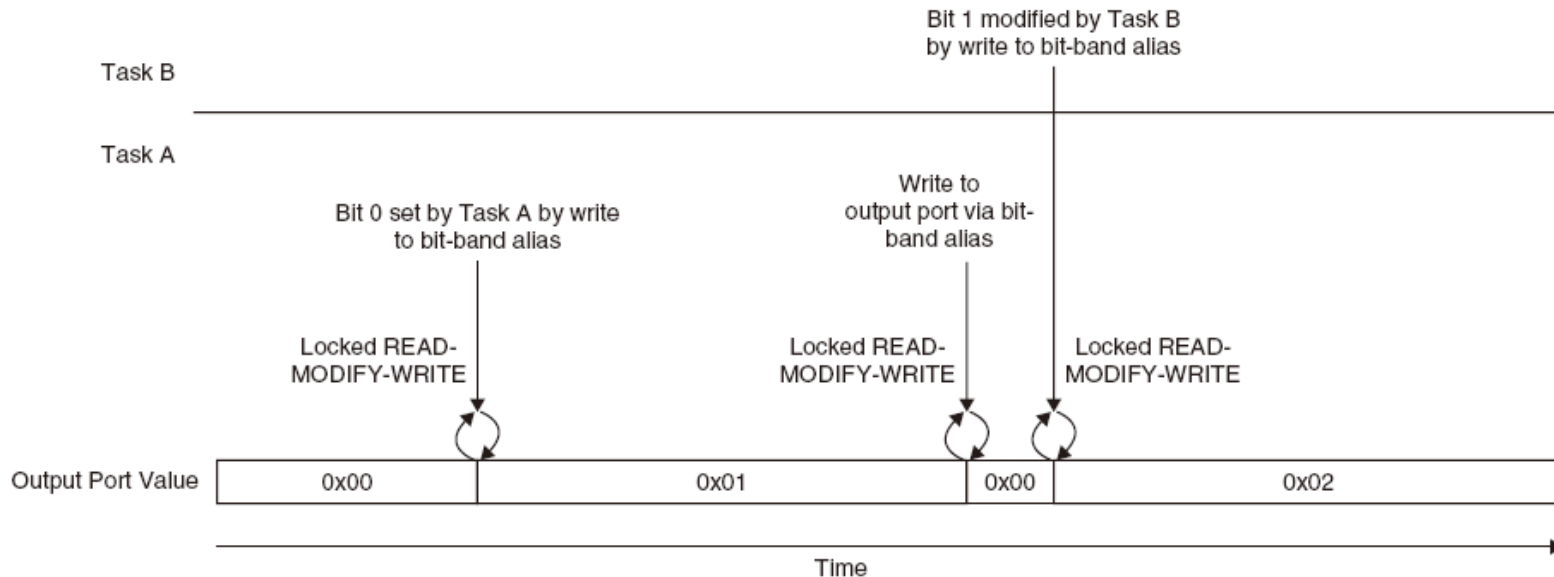

Figure 5.11 Data Loss Prevention with Locked Transfers Using the Bit-Band Feature

Bit-Band Operations in C

- There is no native support of bit-band operation in most C compilers
 - The simplest solution is to separately declare the address and the bit-band alias of a memory location.

```
#define DEVICE_REG0      *((volatile unsigned long *) (0x40000000))
#define DEVICE_REG0_BIT0 *((volatile unsigned long *) (0x42000000))
#define DEVICE_REG0_BIT1 *((volatile unsigned long *) (0x42000004))
...
DEVICE_REG0 = 0xAB; // Accessing the hardware register by normal
                    // address
...
DEVICE_REG0 = DEVICE_REG0 | 0x2; // Setting bit 1 without using
                                // bitband feature
...
DEVICE_REG0_BIT1 = 0x1; // Setting bit 1 using bitband feature
                        // via the bit band alias address
```

Bit-Band Operations in C

- C macros can make accessing the bit-band alias easier

```
// Convert bit band address and bit number into
// bit band alias address
#define BITBAND(addr,bitnum) ((addr & 0xF0000000)+0x20000000+((addr &
    0xFFFFF)<<5)+(bitnum <<2))
// Convert the address as a pointer
#define MEM_ADDR(addr) *((volatile unsigned long *) (addr))

...
MEM_ADDR(DEVICE_REG0) = 0xAB; // Accessing the hardware
                             // register by normal address

...
// Setting bit 1 without using bitband feature
MEM_ADDR(DEVICE_REG0) = MEM_ADDR(DEVICE_REG0) | 0x2;

...
// Setting bit 1 with using bitband feature
MEM_ADDR(BITBAND(DEVICE_REG0,1)) = 0x1;
```

Miscellaneous features

Unaligned Transfers

- The Cortex-M3 supports unaligned transfers on single accesses.
- Data memory accesses can be defined as aligned or unaligned.

Structure management example

Unaligned Transfers

1. Word size, the address is not a multiple of 4.

	Byte 3	Byte 2	Byte 1	Byte 0
Address N+4				[31:24]
Address N	[23:16]	[15:8]	[7:0]	

Unaligned Transfer Example 1

	Byte 3	Byte 2	Byte 1	Byte 0
Address N+4			[31:24]	[23:16]
Address N	[15:8]	[7:0]		

Unaligned Transfer Example 2

	Byte 3	Byte 2	Byte 1	Byte 0
Address N+4		[31:24]	[23:16]	[15:8]
Address N	[7:0]			

Unaligned Transfer Example 3

Unaligned Transfers

2. Half word size, and the address is not a multiple of 2.

	Byte 3	Byte 2	Byte1	Byte 0
Address N+4				
Address N		[15:8]	[7:0]	

Unaligned Transfer Example 4

	Byte 3	Byte 2	Byte 1	Byte 0
Address N+4				[15:8]
Address N	[7:0]			

Unaligned Transfer Example 5

Unaligned Transfers

- There are a number of limitations:
 - Not supported in Load/Store multiple instructions.
 - Stack operations (PUSH/POP) must be aligned.
 - Exclusive accesses must be aligned.
 - Unaligned transfers are not supported in bit-band operations.
- When unaligned transfers are used, they are actually converted into multiple aligned transfers by the processor's bus interface unit
 - Transparent to application programmers.
 - It takes more clock cycles for a single data access

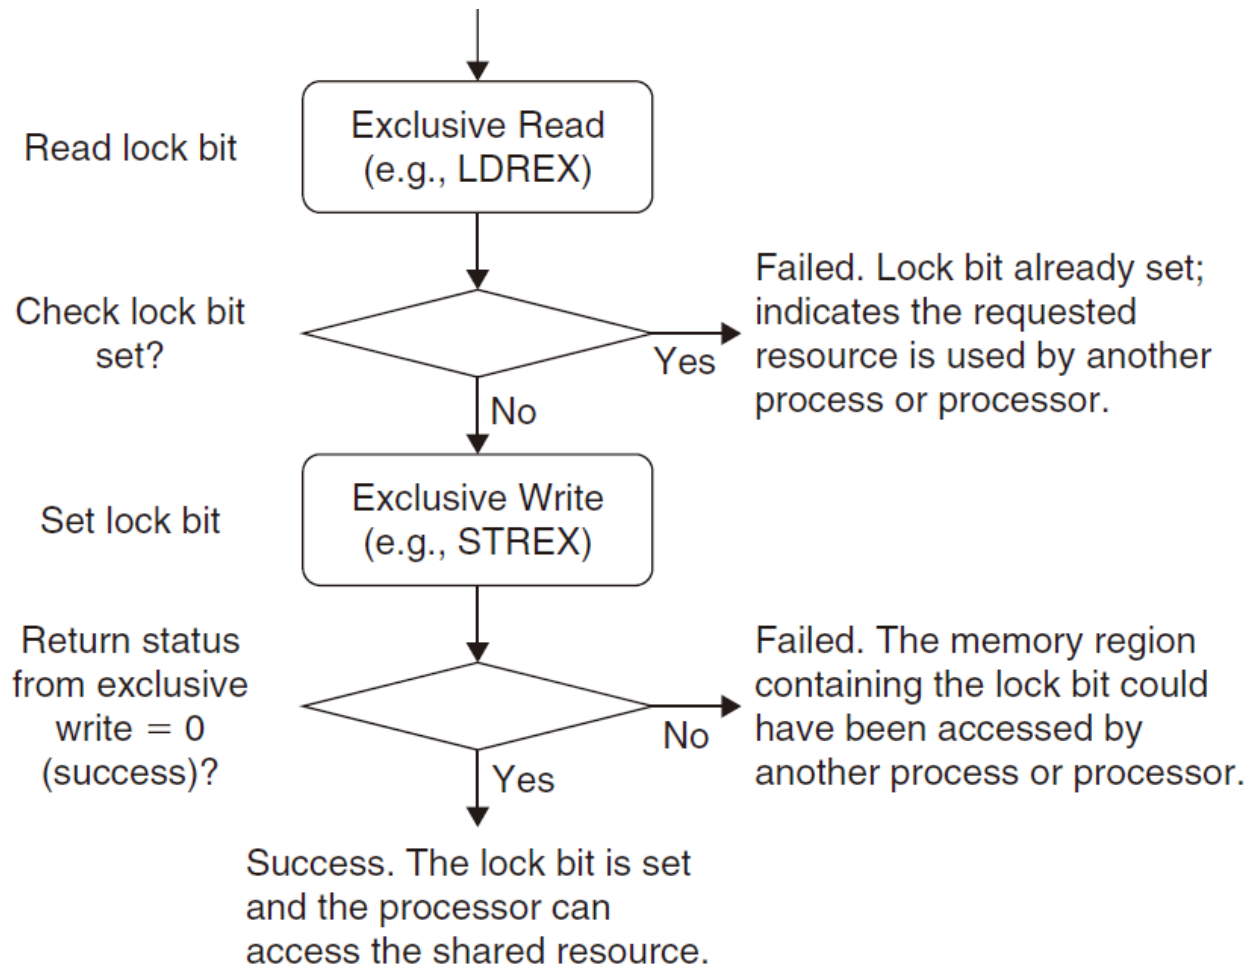

Exclusive Accesses (LDREX,STREX)

- A lock is usually used to safely share resources among tasks and handlers
- Before using a resource, a task should acquire a lock for the resource.
 - Now, other tasks are blocked from using the resources, because they cannot acquire the lock.
- After using the resource, the task should release the lock.

Exclusive Access Instructions

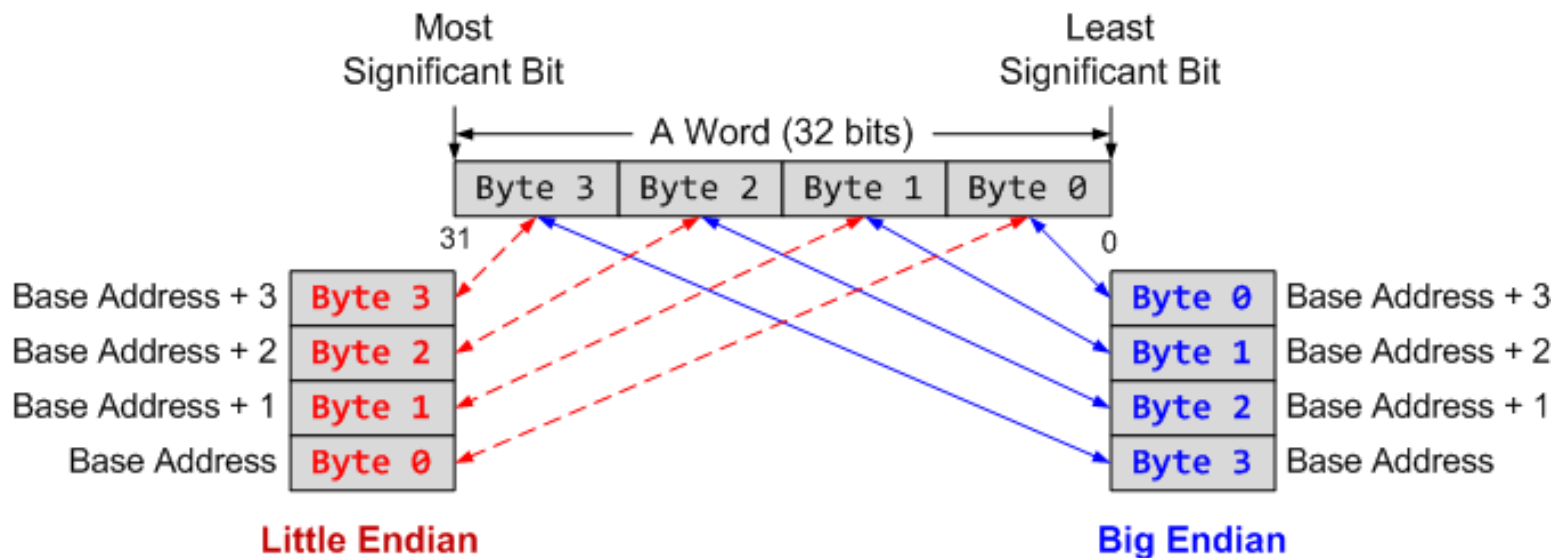

- Exclusive access instructions can check the availability of hardware resource (maybe small memory block for a lock variable)
 - LDREX (word)
 - LDREXB (byte)
 - LDREXH (half word)
 - STREX (word)
 - STREXB (byte)
 - STREXH (half word)

Exclusive Access Operations

Endian Mode

- The Cortex-M3 supports both little endian(recommended) and big endian modes.
 - However, the supported memory type also depends on the design of the rest of the microcontroller (bus connections, memory controllers, peripherals, and so on).
 - Make sure that you check your microcontroller datasheets in detail before developing your software

Endian Mode

- The endian mode is set when the processor exits reset and it cannot be changed afterward.
- Instruction fetches are always in little endian, as are data accesses in the configuration control memory space and the external PPB memory range.
- The data can be easily converted between little endian and big endian using instructions REV/REXH.
